Abstract:

In this research, we reported Fe₃O₄@SiO₂@NCs@Al₂O₃ [FSNCA] nanoparticles as an efficient catalyst for the synthesis of Tetrahydrobenzopyrans (THBPS) in water solvent at room temperature with short reaction time. The catalyst exhibits excellent catalytic activity, selectivity, and recyclability. The nanocatalyst structure was characterized by FT-IR, SEM, XRD, TGA, VSM, and EDS. There are significant advantages of using the FSNCA nanocatalyst such as the primary benefit is the increase in production efficiency. By enabling a one-pot synthesis process, this nanocatalyst decreases the stages required for reaction, reducing time and energy consumption. Furthermore, the possibility of recycling the catalyst contributes to economic efficiency, minimizing waste production, thereby aligning with the principles of green chemistry.

Keywords: Green chemistry; Magnetic nanocatalyst [Fe₃O₄@SiO₂@NCs@Al₂O₃]; Multicomponent reactions; Tetrahydrobenzo[b]pyran

1. Introduction

One of the fundamental principles of green chemistry is the utilization of catalysts in synthesis [1, 2]. The quest for sustainable chemical reactions has led to the development of green catalysts that offer high efficiency, selectivity, and reduced environmental impact. Nanocatalysts have emerged as a promising field due to the unique properties of nanoparticles, including large surface area, high catalytic activity, and ease of recovery [3–12].

Tetrahydrobenzo[b]pyran is an important chemical compound in the class of heterocycles, which has been considered due to its biological properties and activities such as antioxidant and antimicrobial effects. In addition, THBPS are involved in the synthesis of various reactions, making them very important in the pharmaceutical and chemical industries. They are used as drugs, anticancer agents, antibacterial agents, antifungal agents, and antiviral agents [13–25]. Due to the importance of pyrane derivatives, significant research efforts have been devoted in recent years to

the development of new synthetic methods for the synthesis of these compounds. However, these methods have some drawbacks such as: long reaction times, high temperatures, tedious work-up, and in some cases, environmental pollution, and require the use of expensive devices.

As the synthesis of THBPS is a vital process in the chemical industry, the use of suitable catalysts in this process is of great importance. In this research, Fe₃O₄@SiO₂@NCs@Al₂O₃ [FSNCA] was synthesized as an efficient and recyclable nanocatalyst, and then this catalyst was successfully used in the efficient one-pot synthesis of THBPS in a green and high-yield method. The nanocatalyst used in this study consists of three different layers obtained through synthesis and coating processes. FSNCA nanocomposite is a heterogeneous catalyst that has shown excellent performance in various THBP derivatives. FSNCA nanocatalyst consists of a magnetite core (Nano-Fe₃O₄), SiO₂ intermediate layer, nanocellulose and Al₂O₃ nanoparticles. Cellulose is a non-toxic, and biocompatible renewable raw material. Al₂O₃ provides active sites for the

synthesis of THBPS and increases the catalytic ability of the compound.

Also, using water as a solvent eliminates the need for harmful organic solvents. In addition, due to the properties of magnetite, the catalyst is easily separated at the end of the reaction, reducing waste. Also, due to the affordability of the raw materials and the high recycling rate, $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}@\text{Al}_2\text{O}_3$ remains a cost-effective catalyst (Scheme 1).

2. Experimental

2.1 General

The progress of the reactions was checked by thin-layer chromatography (TLC) using UV light. The products were characterized by FT-IR spectra recorded on a BRUKER-ALPHA spectrometer on a KBr disc.

2.2 Synthesis of green nanocatalyst $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}@\text{Al}_2\text{O}_3$ [FSNCA]

Nano- $\text{Fe}_3\text{O}_4@\text{SiO}_2$ was synthesized based on our previous reports in papers 1 and 2. In a flask, nanocellulose (1.000 g) was added to Water: EtOH (1:1) under stirring for 10 min. Then magnetic nanoparticles (0.5 g) were added and mixed under stirring for 1 hour at room temperature. Then, the $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}$ were collected by an external magnet and then washed with H_2O ($2 \times 5\text{mL}$). Functionalized Nano- Al_2O_3 on $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}$ nanoparticles was prepared by the addition of the $\text{Al}(\text{O}-i\text{pr})_3$ (1 mmol) to $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}$ (1.000 g) and grinded at room temperature for 5 minutes. Then aloe vera extract was added to the reaction mixture and grinded at room temperature for 20 minutes. The resulting $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}@\text{Al}_2\text{O}_3$ was collected by an external magnet after washing with H_2O

($2 \times 5\text{mL}$) and drying at room temperature (Scheme 2).

2.3 General procedure for the synthesis of THBPS derivatives(4a-4p)

In a flask, malononitrile (1 mmol), aromatic aldehyde (1 mmol), 5,5-dimethylcyclohexane-1,3-dione or 1,3-cyclohexanedione (1 mmol), FSNCA (25 mg) and H_2O (2.0 mL) were grinded at room temperature and the completion of the reaction was monitored by TLC. Then, water (5 mL) was added into the reaction mixture and the nanocatalyst was separated from the product by using an external magnet. The product was purified by recrystallization in ethanol (96%). Also, FSNCA was washed with deionized water ($2 \times 5\text{mL}$) and dried at room temperature. A range of the different THBPS derivatives were synthesized with excellent yields (Table 1).

2.4 Spectral data of compound (4a)

2-amino-7,7-dimethyl-5-oxo-4-phenyl-5,6,7,8-tetrahydro-4H-chromene-3-carbonitrile (4a); IR (KBr, cm^{-1}): 3410 cm^{-1} , 3327 cm^{-1} , 2221 cm^{-1} , 1671 cm^{-1} , 1211 cm^{-1} , 742 cm^{-1} . ^1H NMR (500.13 MHz, DMSO); 2.07 (d, $J=16.1$ Hz, 1H), 2.20 (d, $J=16.1$ Hz, H), 2.41-2.54 (m, 2H), 4.11 (s, 1H), 6.91 (s, 2H), 7.09 (d, $J=7.4$ Hz, 2H), 7.17 (t, $J=7.4$ Hz, 1H) 7.23 (t, $J=7.5$ Hz, 2H). ^{13}C NMR (125.75 MHz, DMSO); 195.4, 162.4, 159.3, 144.2, 129.3, 128.0, 127.2, 121.7, 113.6, 58.4, 51.9, 34.2, 32.5, 28.2, 27.6.

3. Results and discussion

The synthesis of $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}@\text{Al}_2\text{O}_3$ nanocatalyst begins with the co-precipitation of iron salts, FeCl_2 , and FeCl_3 , this result in the formation of magnetite nanoparticles. Fe_3O_4 acts as a magnetite core in the

Scheme 1. Green synthesis of Tetrahydrobenzo[b]pyran using $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}@\text{Al}_2\text{O}_3$ as a green catalyst.

Scheme 2. Clean synthesis of multilayer magnetite $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}@\text{Al}_2\text{O}_3$ as a green catalyst.

Table 1. Catalyst optimization for the synthesis of THBP in H₂O at room temperature.

Entry	Catalyst	Time (min)	Yield(%)
1	FSNCA(25 mg)	10	95

7	Magnetic Cellulose(25 mg)	10	42
8	Fe ₃ O ₄ @SiO ₂ (25 mg)	10	36

Fe₃O₄@SiO₂@NCs@Al₂O₃ nanocatalyst for easy separation and recyclability of the catalyst. The addition of tetraethyl orthosilicate (TEOS) to the reaction mixture leads to the deposition of a layer of silica (SiO₂) around Fe₃O₄ nanoparticles. The SiO₂ shell acts as a protective layer and enhances the catalyst's durability due to its excellent thermal and chemical stability. In addition, the presence of SiO₂ provides an ideal surface for further functionalization. Nanocellulose was added to the system as a biopolymer by dispersing nanocellulose in the reaction mixture, NCs a natural polymer, serves as a linker material in the Fe₃O₄@SiO₂@NCs@Al₂O₃ nanocatalyst. Its unique structure and abundant hydroxyl groups enable strong interaction with both the Fe₃O₄ core and SiO₂ shell. This linker role enhances the stability of the overall nanocatalyst, preventing the separation of active species during catalytic reactions. Finally, the addition of the Al(O-*i*pr)₃, allows the deposition of an alumina layer (Al₂O₃) on Fe₃O₄@SiO₂@NCs nanoparticles. The presence of Al₂O₃ contributes to the mechanical strength, and durability of the nanocatalyst and in enhancing the overall activity of this nanocatalyst, which makes it especially suitable for catalytic reactions. It also provides sites for reactions, thus increasing the overall catalytic activity. The resulting catalyst exhibits a core-shell structure, with magnetite, silica, nanocellulose, and alumina layers, offering unique properties for various catalytic applications. The catalyst structure was characterized by SEM (Figure 1), FT-IR (Figure 2 (a-c)), XRD (Figure 3 (a-c)), EDS (Figure 4), VSM (Figure 5 (a-c)) and TGA (Figure 6).

3.1 Scanning electron microscope (SEM) analysis

First, the catalyst morphology was analyzed by SEM (Figure 1). The SEM image and histogram confirmed that they exist as core-shell structures with an average size range of 44 nm.

**Figure 1.** Scanning electron microscope (SEM) and histogram of Fe₃O₄@SiO₂@NCs@Al₂O₃ nanocatalyst.

3.2 FT-IR analysis

The FT-IR spectra of (a)Fe₃O₄ (b)Fe₃O₄@SiO₂ and (c)Fe₃O₄@SiO₂@NCs@Al₂O₃ were recorded and are given below (Figure 2 (a-c)). The Fe-O bond stretching appeared at around 400-600 cm⁻¹ in Fe₃O₄ magnetite nanoparticles and the absorbance peaks at around 1114cm⁻¹ are assigned to Si-O in silicon dioxide groups (Figure 2 (a-b)). After the immobilization of Al₂O₃ NPs on Fe₃O₄@SiO₂@NCs (Figure 2 c), a broad band at 3000-3500 cm⁻¹ is assigned to the stretching vibrations of O-H groups. The absorption bands at 1000-1200 cm⁻¹ are assigned to stretching vibrations of C-O bonds in nanocellulose and Si-O-C in silicon dioxide groups which coated by nanocellulose. The absorption band around 400-600 cm⁻¹ are assigned to Fe-O bond stretching in Fe₃O₄ magnetite nanoparticles. Also, the absorption band around 700-1000 cm⁻¹ are assigned to the Al-O-C band for Al₂O₃ attached to nanocellulose.

3.3 X-ray Diffraction Spectroscopy (XRD) analysis

Fe₃O₄@SiO₂@NCs@Al₂O₃ nanoparticles were analyzed by X-ray Diffraction Spectroscopy (XRD) (Figure 3 (a-c)). The XRD pattern clearly shows the structure of the catalyst. The diffraction peaks at around 18.3°, 30°, 35.4°, 43.05°, 53.4°, 56.9°, and 62.5° are corresponded to the (1 1 1), (2 2 0), (3 1 1), (4 0 0), (4 2 2), (5 1 1) and (4 4 0) surfaces, which are readily recognized in the XRD patterns and show good agreement with the cubic structure of Fe₃O₄ (JCPDS File No. 19-0626). The presence of amorphous SiO₂ is clearly indicated by a broad signal around 22.5°, suggesting that the nanoparticles are coated with silica. The diffraction

**Figure 2.** FT-IR spectrum of (a) Fe₃O₄, (b) Fe₃O₄@SiO₂, (c) Fe₃O₄@SiO₂@NCs@Al₂O₃.

Figure 3. XRD patterns of (a) SiO_2 , (b) $\text{Fe}_3\text{O}_4@ \text{SiO}_2$, (c) $\text{Fe}_3\text{O}_4@ \text{SiO}_2@ \text{NCs}@ \text{Al}_2\text{O}_3$.

peaks 16.44 and 22.17 indicate the presence of nanocellulose. Also, the diffraction peaks at 35.1° , 37.8° , 43.4° , 57.5° , and 66.5° correspond to the (1 0 4), (1 1 0), (1 1 3), (1 1 6), and (2 1 4) surfaces and showing good agreement with the rhombohedral (corundum) alumina phase (JCPDS File No. 46-1212).

3.4 EDS analysis

In the EDS analysis (Figure 4) clearly indicates the presence of iron, oxygen, silicon, carbon, and aluminum in the structure of the catalyst. Therefore, the above results fully confirmed the synthesis of the nanocatalyst.

3.5 VSM analysis

In the VSM analysis of the nanocatalyst [$\text{Fe}_3\text{O}_4@ \text{SiO}_2@ \text{NCs}@ \text{Al}_2\text{O}_3$] (Figure 5 (a–c)), the nanocatalyst exhibited a superparamagnetic behavior due to zero remanence since the hysteresis loop was not observed. The magnetic property of the nanocatalyst is sufficient for separation using a simple external magnet. According to (Figure 5 a), the highest saturation magnetization belongs to Fe_3O_4 nanoparticles. In addition, the curves showed a decrease in saturation magnetic values for $\text{Fe}_3\text{O}_4@ \text{SiO}_2$. The lower MS value for $\text{Fe}_3\text{O}_4@ \text{SiO}_2$ is due to the presence of non-magnetic silica on the surface of the Fe_3O_4 nanopar-

Figure 4. EDS spectrum of $\text{Fe}_3\text{O}_4@ \text{SiO}_2@ \text{NCs}@ \text{Al}_2\text{O}_3$.

Figure 5. VSM diagram (a) Fe_3O_4 , (b) $\text{Fe}_3\text{O}_4@ \text{SiO}_2$ (c) $\text{Fe}_3\text{O}_4@ \text{SiO}_2@ \text{NCs}@ \text{Al}_2\text{O}_3$.

ticles [26–28]. It confirms that silica nanoparticles bond on the surface of Fe_3O_4 nanoparticles and the non-magnetic SiO_2 layer is coated on the Fe_3O_4 nanoparticles. It indicates the layer-by-layer coating and the successful synthesis of the $\text{Fe}_3\text{O}_4@ \text{SiO}_2@ \text{NCs}@ \text{Al}_2\text{O}_3$ nanocatalyst.

3.6 Thermal analysis (TGA)

According to the TGA analysis (Figure 6), the stability of $\text{Fe}_3\text{O}_4@ \text{SiO}_2@ \text{NCs}@ \text{Al}_2\text{O}_3$ nanoparticles was observed up to $400\text{--}600^\circ\text{C}$. Additionally, the TGA indicates an initial weight loss due to moisture evaporation from the sample. The main weight loss step in the temperature occurs within the range of $200\text{--}350^\circ\text{C}$, which corresponds to the decomposition of the NCs units on the nanocatalyst. The weight loss at 400°C temperature is attributed to the thermal crystal phase transformation. Additionally, the presence of nanocellulose and alumina layers provides excellent stability of the nanocatalyst under harsh reaction conditions.

3.7 Catalytic activity

To investigate the ability of this catalyst, the three-component reaction involving benzaldehyde (1), malononitrile (2), and dimedone (3) was chosen as a model reaction to produce THBP (4a) (Scheme 3). Then, the reaction conditions were optimized by various catalysts and solvents

Figure 6. TGA analysis of $\text{Fe}_3\text{O}_4@ \text{SiO}_2@ \text{NCs}@ \text{Al}_2\text{O}_3$.

Scheme 3. Green synthesis of THBPS by using FSNCA nanocatalyst.

(Table 1, Table 2). This nanocatalyst exhibited high selectivity, excellent yield (95%), efficiency, and high purity in a short reaction time (10 minutes), green solvent (H_2O), and low temperature (room temperature). After identifying the optimal conditions, other pyran derivatives were synthesized using the catalyst (Table 3).

3.8 Suggested mechanism for the synthesis of THBPS by using green catalyst $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}@\text{Al}_2\text{O}_3$

The mechanism involves the formation of intermediate 5, followed by the cyclization, subsequent neutralization, and tautomerization to yield THBPS compounds. The unique structure and composition of the green catalyst $[\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}@\text{Al}_2\text{O}_3]$ facilitate the key steps of this mechanism, leading to enhanced reaction efficiency and selectivity (Scheme 3).

3.9 Catalyst stability and recyclability

Catalyst recyclability is a critical factor in the development of sustainable and environmentally friendly processes. The $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{NCs}@\text{Al}_2\text{O}_3$ nanocatalyst exhibited excel-

lent recyclability, with no significant loss in catalytic activity even after multiple cycles (Figure 7). The nanocatalyst could be separated using a simple external magnet. This feature not only reduces waste generation but also lowers the overall cost of production.

3.10 Hot filtration test

A hot filtration test for Dimedone (1 mmol), benzaldehyde (1 mmol), and malononitrile (1 mmol) model reaction was performed by FSNCA-Catalyst (25 mg). Then, the catalyst was separated and the reaction mixture was monitored and it was found that there was almost no further conversion after catalyst separation. The results clearly confirmed that the nanocatalyst is stable under artificial conditions and can be reused several times without reducing the catalytic activity (Figure 7).

3.11 Comparison of the catalytic efficiency of Fe₃O₄@SiO₂@NCs@Al₂O₃ with other reported catalysts for the synthesis of THBPS

According to Table 4, Fe₃O₄@SiO₂@NCs@Al₂O₃ has emerged as an ideal catalyst for the green synthesis of THBPS due to its unique properties. Fe₃O₄@SiO₂@NCs@Al₂O₃ exhibits superior performance in terms of green reaction conditions, green solvent (H₂O), reaction temperature (room temperature), reaction time (10 minutes), product's purity and excellent efficiency (95%), one-pot grinding-methodology, the absence of side reactions, recovery and reusability of the nanocatalyst. Environmentally friendly, availability, high efficiency, short reaction time, mild reaction conditions, stability and recyclability of the catalyst, and clean separation of the catalyst are the most important features of this method compared to previously reported catalysts.

4. Conclusion

Fe₃O₄@SiO₂@NCs@Al₂O₃ (FSNCA) nanocatalyst offers a sustainable and efficient approach for the synthesis of the Tetrahydrobenzo[b]pyran (THBPS). The unique combination of magnetite, silica, nanocellulose, and alumina provides enhanced catalytic properties and easy separation and recyclability, making it an ideal catalyst for green organic synthesis. The development and application of this green catalyst pave the way for the development of more sustainable and environmentally friendly chemical processes.
